Dear Editor,

We read with interest the review by Cheung and colleagues and agree that existing evidence for the obesity paradox is weak (1). We contend however that benefits of excessive adiposity for osteoporotic fractures are not supported by the literature, despite the authors’ conclusion that obesity protects against fractures.

While obesity defined by body mass index (BMI) is generally associated with lower fracture incidence, fracture risk at specific sites may be increased. In the Global Longitudinal Osteoporosis in Women study, fracture prevalence and incidence were similar for obese and non-obese women, and risk of incident ankle and upper leg fractures were significantly higher in obese (2). Cheung et al note that BMI is a better indicator of lean than fat mass (1) and in over 43,000 Canadian older adults, higher lean mass was positively associated with femoral neck bone mineral density (BMD), whereas fat mass had no effect on BMD and adversely affected femoral strength index (3). Thus, higher lean mass, not fat mass, likely explains positive associations of higher BMI with BMD in older adults.

The authors identified that body fat distribution is more predictive of clinical outcomes than BMI (1), and this may be true for osteoporotic fractures. Men with higher levels of visceral adipose tissue have poorer bone mechanical properties, despite having similar BMD compared with those with low visceral adipose tissue (4). A recent meta-analysis also demonstrated that high waist circumference, a measure of abdominal adiposity, was associated with almost 60% increased relative risk of hip fracture (5).

Finally, while we agree that weight loss in obese older adults is beneficial for cardiometabolic health, clinicians should be aware that weight loss results in declines in muscle and bone mass that may increase falls and fracture risk. Incorporating exercise, particularly resistance training, into weight loss programs can significantly reduce the loss of muscle and bone mass (6), and is therefore strongly recommended for obese older adults.
