Appendiceal adenocarcinoma is a rare gastrointestinal lesion that is rarely invasive of pelvic structures at diagnosis. We present an unusual case of one such lesion that invaded the rectum, which was detected on endoscopy performed for investigation of haematochezia. Involvement of a multidisciplinary team and extensive en bloc resection was able to achieve a curative outcome in this case.

A previously well 59-year-old man presented with a large bleed per rectum. Colonoscopy demonstrated a mid rectal tumour, 10cm from the anal verge. Histology confirmed a moderately differentiated adenocarcinoma. Staging CT highlighted a hyperdense structure extending from the caecal pole into the right pelvis and invading the wall of the rectum, in keeping with a primary appendiceal malignancy.

Staging MRI revealed a high signal upper rectal mass with a craniocaudal height of 42mm that extended into the mesorectal fascia on the right and into the base of the caecum contiguous with the appendix. The tumour invaded the peritoneal reflection adjacent to the iliac arteries and involved the right ureter without obvious bladder invasion. Staging PET scan showed a solitary pelvic mass with no nodal enlargement, peritoneal disease or distant metastases. The patient was discussed at the Lower GI surgical oncology MDT where there was agreement that this was a primary appendiceal malignancy with local invasion and should be managed in line with current guidelines for advanced pelvic malignancy. He proceeded to neoadjuvant long course chemoradiotherapy with 5-fluorouracil and 50.4Gy for five weeks. Restaging imaging demonstrated an interval reduction in size of the known invasive appendiceal cancer. This was followed by definitive surgical resection.
At surgery, ureteric stenting was performed to assist in delineating the plane between the tumour and retroperitoneal structures. The mass was found to arise in the appendix and adhere to the right ureter at the level of the vesicoureteric junction before invading the rectum. En bloc low anterior resection and right hemicolectomy was performed in combination with a partial cystectomy and distal ureterectomy. The ureter was reimplemented in the dome of the bladder. The patient was defunctioned with a covering loop ileostomy. Histopathology demonstrated a pT4bN0 perforated moderately differentiated mucinous adenocarcinoma arising in the distal appendix and directly extending into the rectum. Tumour involved perivesical and periureteric fat but did not invade the right ureter. Postoperative recovery was complicated by a small rectocolic anastamotic leak that resolved with conservative management. The patient was discharged home on day 21 without further complications. He proceeded to further postoperative chemotherapy. His stoma was reversed 17 months following his operation. He is well and recurrence free 18 months later.

Appendiceal adenocarcinoma is a rare gastrointestinal cancer with a reported incidence of 0.2/100000,\(^1\) although it is the commonest appendiceal malignancy.\(^2\) It most commonly presents as an incidental finding at appendicectomy performed for acute appendicitis, although a minority of cases present as a pelvic mass.\(^3\) Such masses can rarely be locally invasive into adjacent pelvic structures, typically the bladder.\(^4\)\(^5\)\(^6\) In the setting of bladder invasion, formation of vesicoappendiceal fistulae has been reported.\(^7\)\(^8\) There is a much smaller literature describing primary appendiceal adenocarcinoma invasive to the rectum at diagnosis, with only one previous reported case.\(^9\) Recommendations regarding management of appendiceal
adenocarcinoma focus primarily on disease confined to the appendix (T3 or less). The management of this type of early appendiceal adenocarcinoma with right hemicolecctiony is essentially uncontroversial.\textsuperscript{10} However, there is paucity of formal guidelines for the management of advanced appendiceal malignancy. The experience of our centre is that this type of advanced complex tumours should be managed in the same manner as other advanced pelvic malignancies. In this case the management plan was formulated in a MDT and the decision to treat with neoadjuvant chemoradiotherapy resulted in a reduction in tumour bulk. A colorectal surgeon and urologist carried out a radical resection to achieve R0 margins. The ongoing follow-up of this patient in a dedicated Lower GI surgical oncology outpatient unit according to the standard colorectal carcinoma surveillance regime will maximise the likelihood that any recurrent disease is detected and managed promptly.\textsuperscript{11}
