14

15 COMMENTARY

16 Rotavirus is a leading cause of morbidity and mortality for neonates and children. Worldwide,  
17 over 200,000 children die from rotavirus gastroenteritis each year (1) and more than 90  
18 million infants still lack access to a rotavirus vaccine (2). Traditional vaccine schedules  
19 administer doses at 8 weeks, 14 weeks and 18 weeks of age. Therefore, neonates are often  
20 exposed to rotavirus before the first dose is given (3). This is of particular importance in low  
21 income countries, where access to vaccine is poor, there is earlier onset of rotavirus disease  
22 and the burden of disease significant (4).

23

24 Current vaccines approved for use are *Rotarix*<sup>TM</sup> (GSK Vaccines, Wavre, Belgium) and  
25 *RotaTeq*<sup>TM</sup> (Merck & Co, Kenilworth, USA). These have not been investigated with a  
26 neonatal dosing schedule. Furthermore, there is evidence of suboptimal vaccine efficacy in  
27 low- and middle-income countries (5).

28

29 RV3-BB is a novel vaccine which has been investigated in early phase trials in Australia (6)  
30 and New Zealand (7). It is developed from a human rotavirus strain, RV3 (G3P[6]) found in  
31 infants with asymptomatic infection. Dosing at birth is likely to be efficacious and safe: RV3-

1 BB P[6] vaccine strains effectively adhere to the newborn gut (8), display minimal  
2 interference from maternal breast milk (9) and are naturally attenuated (2). This strain also  
3 provides heterotypic serologic responses, which may offer cross-protection against other  
4 circulating rotavirus strains (2). Further potential advantages of a neonatal schedule include  
5 improved uptake, particularly in low-income countries.

6  
7 This randomised, double-blind, placebo-controlled trial in Indonesia demonstrated the  
8 efficacy of a human neonatal rotavirus vaccine in preventing severe rotavirus gastroenteritis  
9 before 18 months of age. When administered on a neonatal dosing schedule, RV3-BB had a  
10 vaccine efficacy of 94% at 12 months of age and 75% at 18 months of age. RV3-BB  
11 administered on both the neonatal and infant schedules demonstrated comparable or superior  
12 efficacy to other rotavirus vaccines in low-income countries (2). While the trial was  
13 underpowered to detect rare adverse events, no cases of intussusception were detected within  
14 21 days of vaccine administration. Only one participant in the trial developed intussusception  
15 in the infant-schedule arm; at 8.5 months of age, 114 days after the third dose of vaccine.

16  
17 The authors chose a one-sided alpha level of 0.1. It is unclear why this unconventional  
18 significance level was chosen, perhaps in order to limit the sample size required for the trial.  
19 Nevertheless, the results obtained for the primary outcome and vaccine efficacy had far lower  
20 p values than this, therefore the interpretation of the results is unchanged.

21  
22 This is a large study with rigorous methodology that demonstrates the efficacy of a new  
23 human rotavirus vaccine in a low-income country with high burden of disease. While the  
24 benefits of a neonatal schedule are clear in this setting, the applicability to other settings with  
25 higher vaccine coverage is unknown. Furthermore, there has not been a direct comparison of  
26 this rotavirus vaccine with the other vaccines currently in use. Nevertheless, this vaccine  
27 shows promise for addressing the ongoing global burden of rotavirus disease.
